

## Chapter 1

### Introduction and background

Our goal is to understand the calculation of Gromov-Witten invariants of the space  $\overline{M}_{g,n}(\mathbb{P}^r, d)$ , the moduli space of degree  $d$  maps to  $\mathbb{P}^r$  using techniques of Atiyah-Bott localization. To begin this endeavor, we must explore  $\overline{M}_{g,n}$  first and its intersection theory. This is the space of genus  $g$  Riemann surfaces with  $n$  marked points which was studied by Deligne and Mumford originally. Afterwards, we will introduce the concept of equivariant cohomology and the Atiyah-Bott theorem. The theorem's usefulness will be presented by showing several examples and finally we will apply it to calculate more examples in the setting of the moduli space of maps.

#### 1.1 Moduli of curves

**Definition 1.1.1.** A Riemann surface is a complex analytic manifold of dimension 1.

For every point, there's a neighborhood which is isomorphic to  $\mathbb{C}$  and transition functions are linear isomorphisms of  $\mathbb{C}$ . We will interchangeably say Riemann surface or *smooth compact complex curve*.

**Example 1.1.2.** The following classes define Riemann surfaces.

- (a)  $\mathbb{C}$  itself is a Riemann surface with one chart.
- (b) Any open set of  $\mathbb{C}$  is a Riemann surface.
- (c) A holomorphic function  $f: U \subseteq \mathbb{C} \rightarrow \mathbb{C}$  defines a Riemann surface by considering  $\Gamma_f \subseteq \mathbb{C}^2$ . There's only one chart determined by the projection and the inclusion  $i_{\Gamma_f}$  is its inverse.
- (d) Take another holomorphic function  $f$ , then  $\{f(x, y) = 0\}$  is a Riemann surface such that

$$\text{Sing}(f) = \{\partial_x f = \partial_y f = f = 0\} = \emptyset.$$

This means that at every point the gradient identifies a normal direction to the level set  $f = 0$ . In particular, there's a well defined tangent line. The inverse function theorem guarantees that this is a complex manifold.

(e) Our first compact example is  $\mathbb{CP}^1$ .

As a set, the moduli space  $\mathcal{M}_{g,n}$ 's points are isomorphism classes of genus  $g$ ,  $n$ -pointed Riemann surfaces.

**Example 1.1.3.** The space  $\mathcal{M}_{0,4}$  parametrizes smooth rational curves  $(\mathbb{P}^1, p_1, \dots, p_4)$ . We have that

$$(\mathbb{P}^1, p_1, \dots, p_4) \sim (\mathbb{P}^1, q_1, \dots, q_4)$$

whenever there is exists a Möbius transformation  $T \in \text{PGL}_2$  such that

$$(q_1, \dots, q_4) = (Tp_1, \dots, Tp_4).$$

Any such Möbius transformation is determined by where it maps the points  $0, 1$  and  $\infty$ . With this fact in hand we may map the first 3 points of our curve to  $0, 1, \infty$ , and let the last one map to an arbitrary but fixed  $t$ :

$$(Tp_1, \dots, Tp_4) = (0, 1, \infty, t), \quad t \in \mathbb{P}^1.$$

At the level of equivalence classes this means:

$$[(\mathbb{P}^1, p_1, \dots, p_4)] = [(\mathbb{P}^1, 0, 1, \infty, t)]$$

and so every equivalence class is determined by a unique  $t \in \mathbb{P}^1$ . We call this value the cross-ratio of  $(p_1, \dots, p_4)$ . The Möbius transformation in question is

$$T(z) = \frac{(z - p_1)(p_2 - p_3)}{(z - p_3)(p_2 - p_1)}$$

and the image of  $p_4$ ,  $t = T(p_4)$  is the aforementioned cross-ratio of  $p_1, \dots, p_4$ . This leads us to see that

$$\mathcal{M}_{0,4} \simeq \mathbb{P}^1 \setminus \{0, 1, \infty\}.$$

**Example 1.1.4.** The space  $\mathcal{M}_{1,1}$  parametrizes *elliptic curves*.

Any such curve is isomorphic to

$$\mathbb{C} / L, \quad L = \mathbb{Z}u + \mathbb{Z}v, \quad \text{where } u, v \in \mathbb{Z},$$

and the image of the origin under the quotient map is the natural choice for the marked point. We have that two lattices  $L_1, L_2$  determine the same elliptic curve whenever

$$\exists \alpha \in \mathbb{C}^\times (L_2 = \alpha L_1).$$

So that

$$\mathcal{M}_{1,1} = \{\text{lattices}\} / \mathbb{C}^\times$$

but we can be more precise!

Explicitly, if

$$L = \text{gen}_{\mathbb{Z}}(u, v) \Rightarrow \tilde{L} = \frac{1}{u}L = \text{gen}_{\mathbb{Z}}(1, \tau).$$

This quantity  $\tau$  always lies in the upper half plane when

$$\arg(v) > \arg(u) \bmod [-\pi, \pi]$$

which means that  $\tau \in \mathbb{H}$  determines  $[\mathbb{C}/L]$ . Let us apply two  $\mathrm{SL}_2(\mathbb{Z}) = \mathrm{gen}(S, T)$  actions on  $\tau$  which will leave the quotient unchanged:

$$\begin{cases} T: \tau \mapsto \tau + 1 = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} \circ \tau = \frac{\tau + 1}{0\tau + 1}, \\ S: \tau \mapsto -\frac{1}{\tau} = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} \circ \tau = \frac{0 - 1}{\tau + 0}. \end{cases}$$

Then observe that the lattices

$$\mathrm{gen}_{\mathbb{Z}}(1, T \circ \tau) \quad \text{and} \quad \mathrm{gen}_{\mathbb{Z}}(1, S \circ \tau)$$

give us the same quotient. From this we can be more specific and say

$$\mathcal{M}_{1,1} = \mathbb{H} / \mathrm{SL}_2(\mathbb{Z}).$$

## Stable curves

**Definition 1.1.5.** A genus  $g$ ,  $n$ -pointed stable curve is a projective curve  $(C, p_1, \dots, p_n)$  satisfying the following properties:

- (a) Marked points  $p_i$  are all distinct and lie in the smooth locus of the curve.
- (b) Singularities of  $C$  are, at worst, nodal.
- (c) Each connected component of the curve with genus  $g_i$  and  $n_i$  nodes or marks satisfies

$$2g_i - 2 + n_i > 0.$$

The moduli space of curves,  $\overline{\mathcal{M}}_{g,n}$ , parametrizes stable curves with arithmetic genus  $g$  and  $n$  marked points. This means that any point of the moduli space is an equivalence class of curves up to homeomorphism type.

**Example 1.1.6.** The moduli space  $\overline{\mathcal{M}}_{0,4}$  parametrizes stable rational curves with 4 marks.

Inside this moduli space lies the dense open subset  $\mathcal{M}_{0,4}$  of smooth rational curves with 4 marks. When we let  $t \rightarrow 0, 1$  or  $\infty$ , this appears to break the condition that marks must be distinct. But what happens is that we blow up the curve at that point of collision and attach our marks the exceptional divisor at different places. The point of contact then becomes a node and we do, indeed, get a stable curve. need to explain better. I think I should talk about Riemann surfaces instead and then say R.S. is like a stable curve... How?

## 1.2 The tautological ring

- (a)  $\psi, \lambda$  classes
- (b) Intersection product Examples

- (c) Projection formula
- (d) String and Dilaton relations
- (e) Integral examples

### **1.3 Moduli space of maps**

## Chapter 2

# Equivariant Cohomology and Localization

## 2.1 Basics of equivariant cohomology

- (a) Borel Construction of Equivariant Cohomology
- (b) Examples of point equivariant Cohomology
- (c) Equivariant Cohomology of projective space

## 2.2 Atiyah-Bott Localization

- (a) Example of  $H_T^*(\mathbb{P}^r)$  through Localization
- (b) Toric varieties Euler characteristic via Atiyah-Bott
- (c) Hodge integral  $\int_{\overline{M}_{0,2}(\mathbb{P}^2,1)} \text{ev}_1^*([1:0:0])\text{ev}_2^*([0:1:0])$  via localization.
